

Moral Approach-Avoidance Tendencies as a Measure of Implicit Moral Attitudes and Motivation

Sanskriti Purohit, Natalie Smith, Kristi Van Meter,
Paul McKee

MAAT: Do humans exhibit moral approach-avoidance tendencies (and can they serve as proxies for implicit attitudes)?

**American
Red Cross**

**R-MAAT: To what extent does race
interact with moral
approach-avoidance tendencies?**

What we know so far: It is unclear

What have we done so far: MAAT Study 1

MAAT

- Stimuli are either: 3-word **Phrases** or **Images**.
- Stimuli are two of three **Moral Valence** categories:
 - **Good** and **Bad** , **Good** and **Neutral**, or **Neutral** and **Bad**
- Stimuli **Background Color** are either:
 - **Yellow** or **Blue**
- Stimuli are **Evaluated** by either:
 - **Implicit** (responding to **Background Color**) or **Explicit** (responding to **Moral Valence**)

Moral Valence Examples

Morally Good

Example: Saving a life

Morally Neutral

*Example: Eating a pizza,
Stubbing a toe*

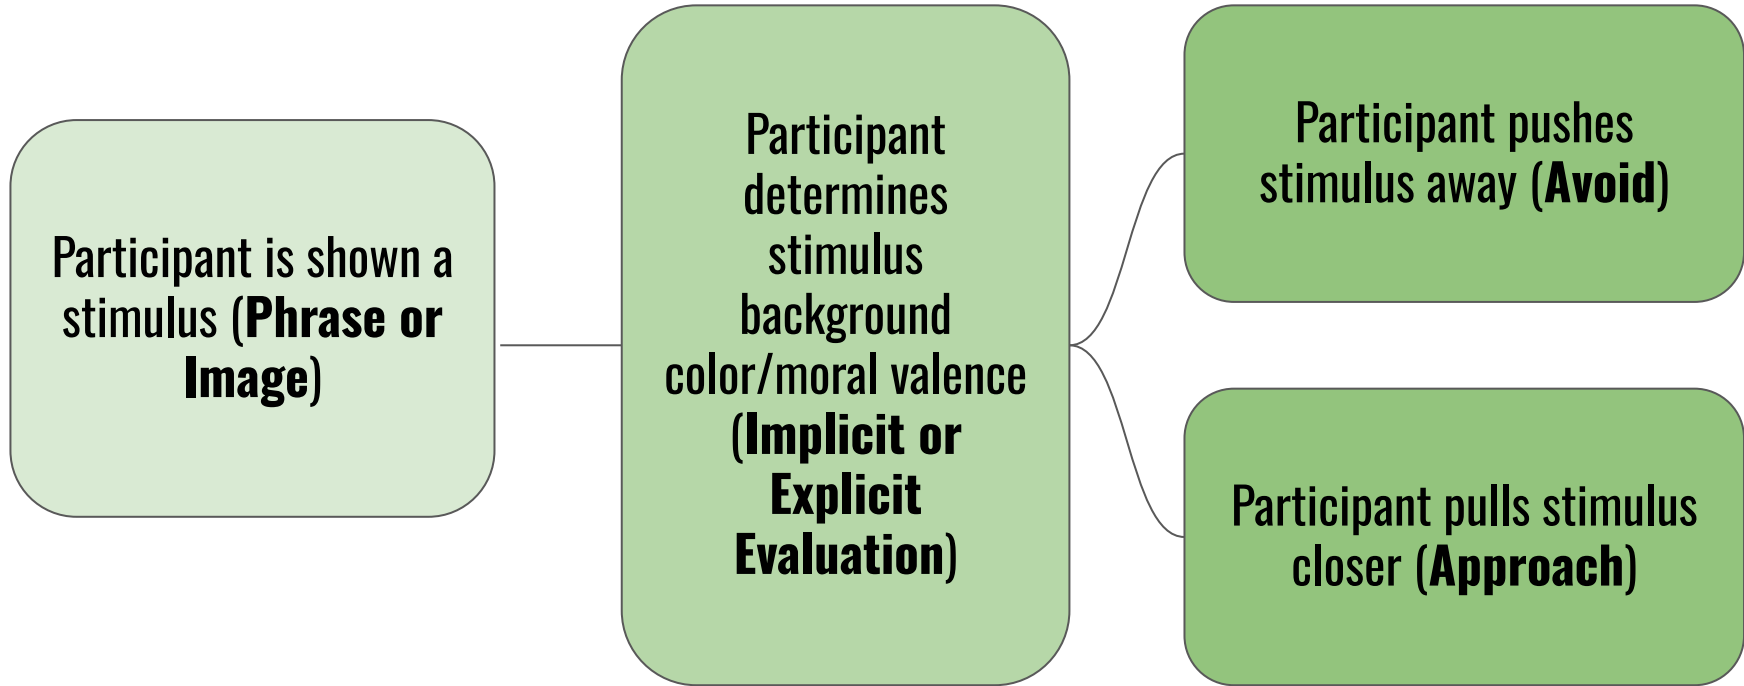

Morally Bad

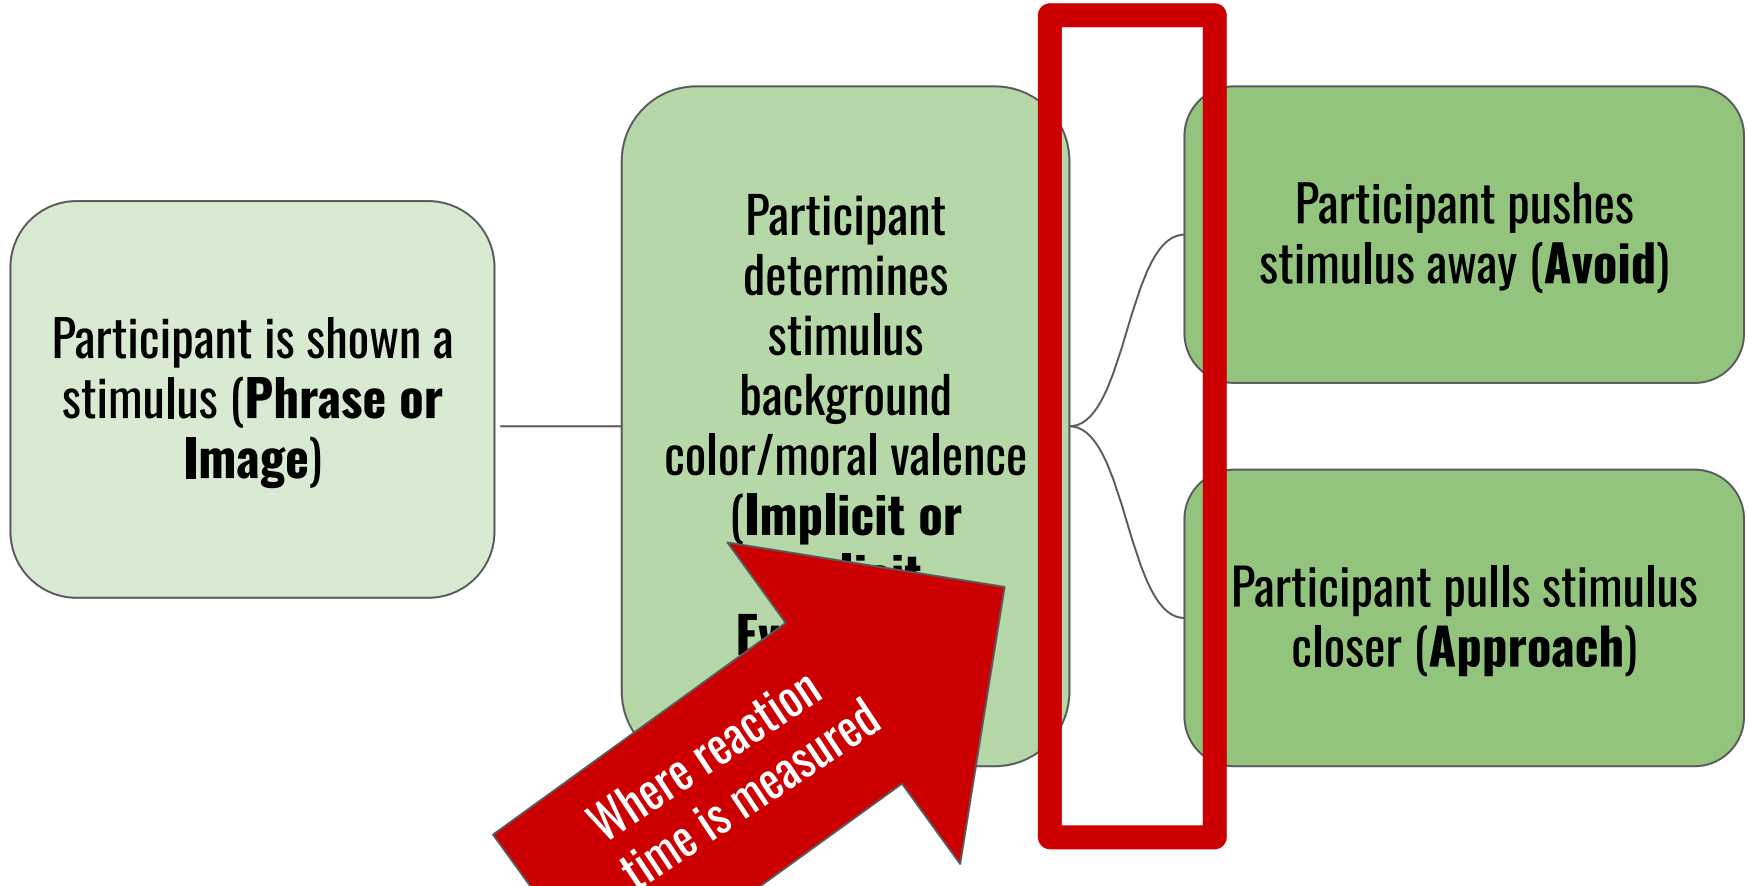

Example: Robbing a store

$$E(\text{Clock}) +$$

LINEAR MIXED EFFECTS MODELS

$$\text{Outcome}_i = E(\text{Outcome})_i + AX + BY + \text{Error}$$

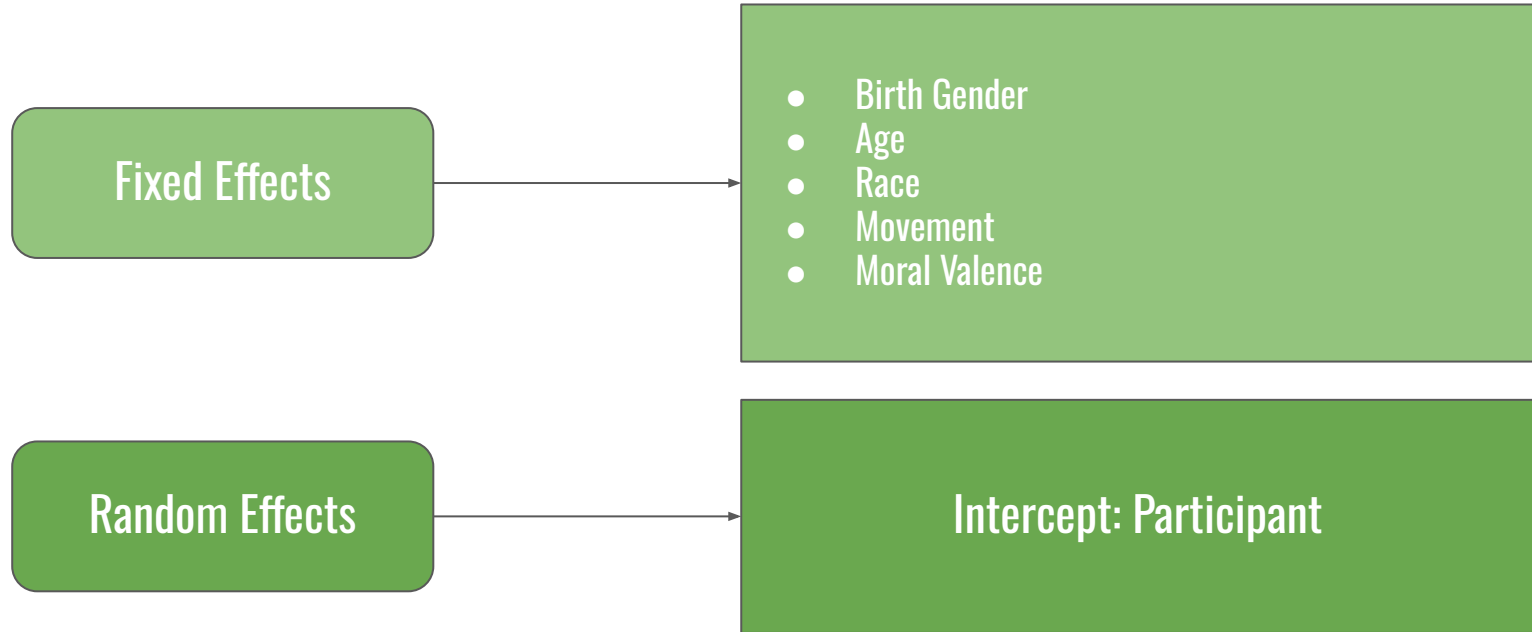

LINEAR MODELS

$$\text{Outcome}_i = E(\text{Outcome})_i + AX + BY + \text{Error}$$

$$E(\text{Outcome})_i = E(\text{Outcome}) +$$

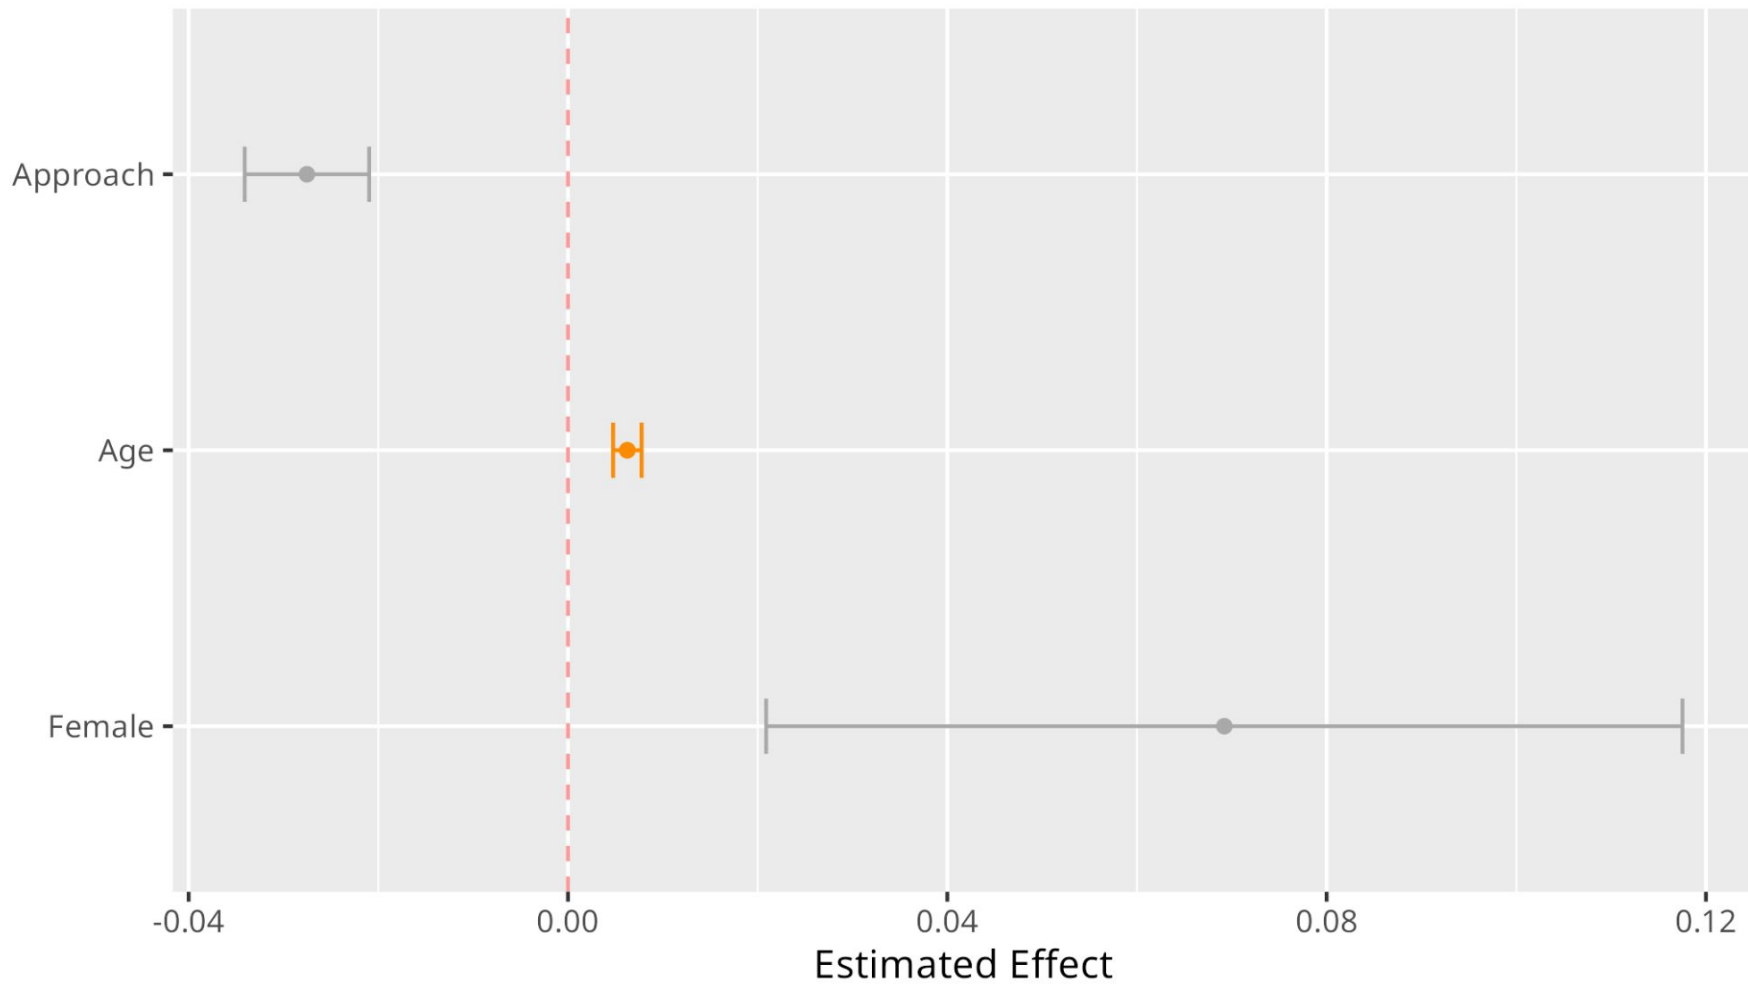

MODEL RESULTS

Linear Mixed Effects Models: Implicit (Phrases)

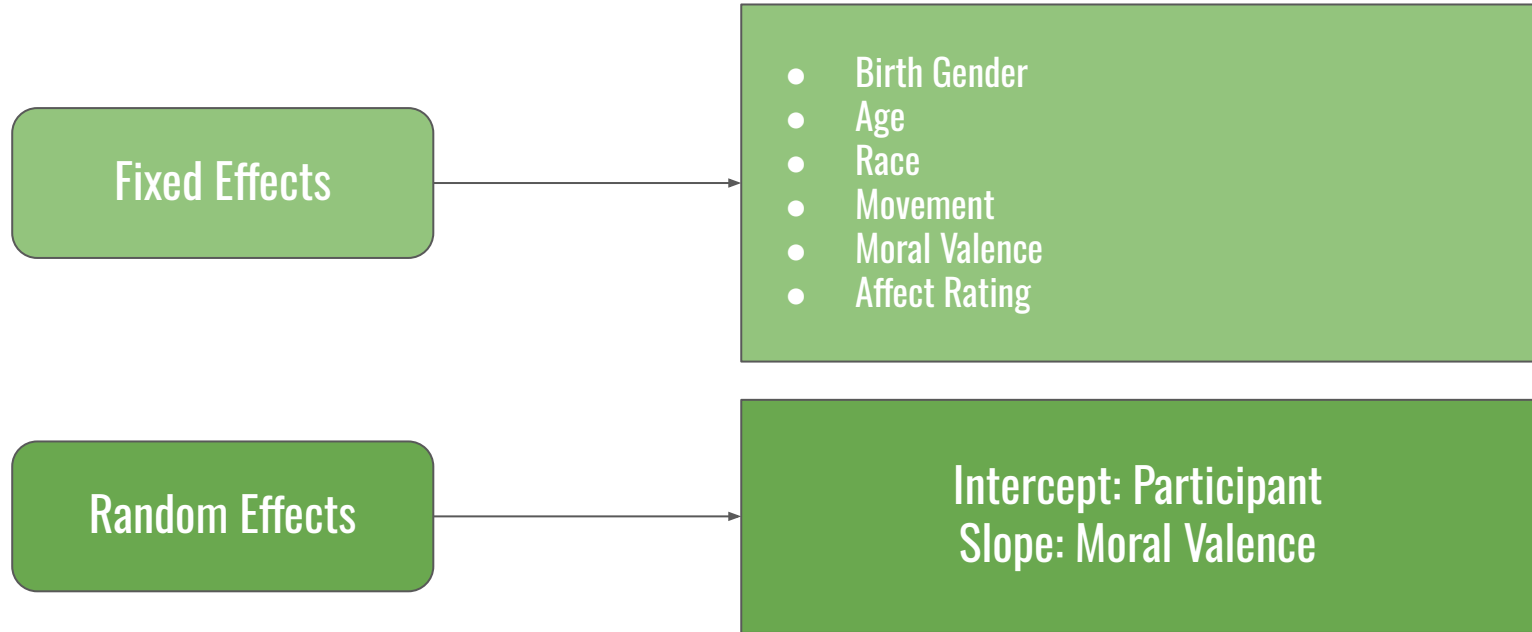

Approaching is faster than avoiding by approximately 3%

Linear Mixed Effects Models: Explicit (Phrases)

On average, compared to Neutral-rated phrases, responses to Immoral-rated phrases are faster by 8.6%.

On average, compared to Neutral-rated phrases, responses to Moral-rated phrases are faster by 7.6%.

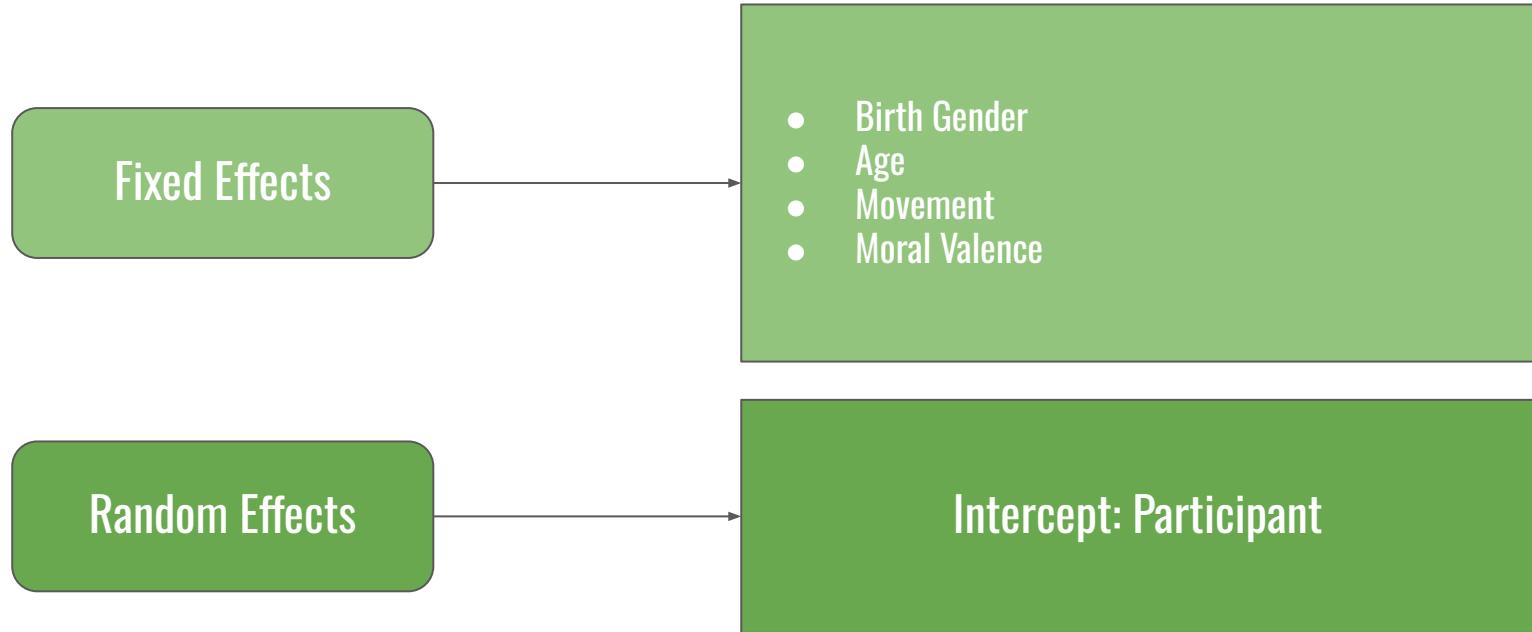

With 1 unit increase in Affect Rating, there is a 1 millisecond increase in the response time.

Linear Mixed Effects Models: Implicit (Images)

On average, compared to Neutral-rated phrases, responses to Moral-rated phrases are faster by 1.9%.

Approaching is faster than avoiding by approximately 1.6% (a decrease compared to phrases)

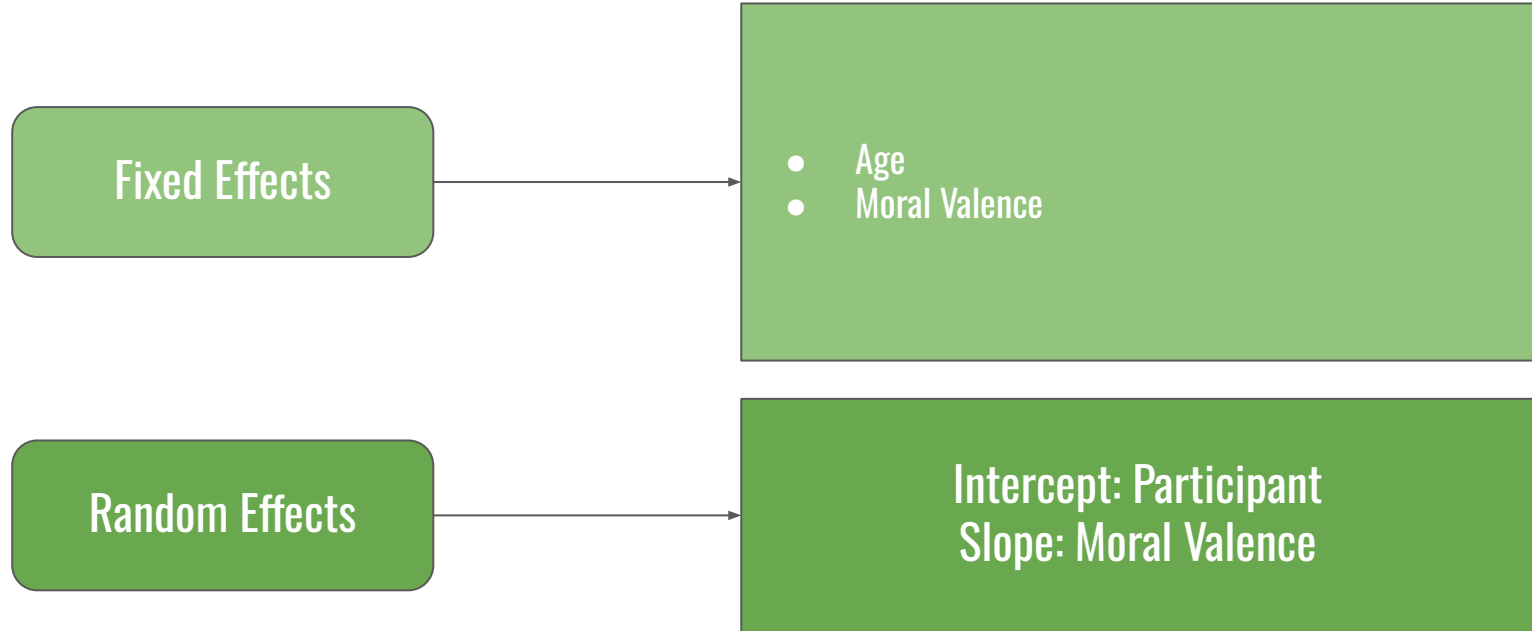

On average, compared to Neutral-rated phrases, responses to Immoral-rated phrases are faster by 1%.

Linear Mixed Effects Models: Explicit (Images)

On average, compared to Neutral-rated phrases, responses to Immoral-rated phrases are faster by 17.3%.

On average, compared to Neutral-rated phrases, responses to Moral-rated phrases are faster by 12.9%.

There might be a relationship, but is it predictive?:
Supervised ML Prediction of Response Time

Performance is Poor (particularly for images) and Moral Rating Does Little to Nothing in Predicting Response Time

	R2	MAE
Ridge	0.069	383.15
RF	0.072	340.67
SVR ➔	0.143	292.59
XGBoost	-0.034	335.63

	R2	MAE
Ridge	0.027	396.68
RF ➔	0.029	364.24
SVR	-0.009	371.82
XGBoost	-0.044	358.82

Are these the 'right' stimuli?:
Unsupervised ML Validation

Morally **Good** = the most pleasant and medium complex

Morally **Bad** = the least pleasant and least complex

Next Steps: MAAT Study 1

Optimize machine learning approaches

- Supervised: Predict specific stimuli, moral category of stimuli
- Unsupervised: More models to improve clustering

Develop a simulation-based power analysis

Examine asymmetries/differences in inferential and predictive relationships

- Compare participant-assigned moral valence to our assigned moral valence

**Thank you for your time and interest.
Any questions?**
